I. System Description

In this example, we will capture LIDAR data from the RP LIDAR A2 on the QCar platform, send the data to a polar plot, and generate a point cloud map. The process is shown in Figure 1.

Figure 1. Component diagram

In addition, a timing module will be monitoring the entire application's performance. The Simulink implementation is displayed in Figure 2 below.

II. Running the example

Check the user guide **IV - Software - Simulink** for details on deploying Simulink models to the QCar as applications.

As your room size may vary, change the `maximumDistance (m)` parameter within the `pointCloud` subsystem accordingly, up to a maximum of 4m (corresponding to an 8 x 8 m room). Figure 3 shows the typical output expected when running this example.

III. Details

1. Capturing LIDAR data

The RP LIDAR A2 reads data in a clockwise manner, starting from a position opposite to the data cable attached to it. On the QCar platform, this corresponds to the +y axis. To correct this, the **captureLIDAR** subsystem corrects the order of the data to start at the front and orient counterclockwise to follow standard convention in the **bodyFrameAdjustmentOnCapture** function.

2. Saturating the distances data meaningfully

To limit the scope of the data to a range, the **distances** data is dynamically saturated using the **maximumDistance** parameter. The **findXYContour** function then converts the **distance/heading** data pairs to **X Y** pairs. However, we would like the **X Y** points corresponding to the **maximumDistance** to not show up within the point cloud itself, as they simply correspond to a maximum range and not physical obstacles. To do so, the **findXYContour** also drops data points that are equal to the **maximumDistance** parameter.

3. Generating the point cloud

This function first decays the existing map to 90%, thereby slowly erasing older data. The **X Y** data points in meters are converted to pixel scale **pX** and **pY** using a **gain** of 50 px/m for a map of size **dim** up to 400 pixels wide and tall (or 8m x 8m). Check out the documentation of MATLAB's **sub2ind** for information on how the (row, col) pairs in (**pX**, **pY**) are converted to indices where the point cloud map will be set to **1**. Adjust the **decay** parameter to change the rate of update of the map. Note that you can do this online while the application is deployed.

4. Performance considerations

To improve performance, we only create a blank map on the first call by the use of persistent MATLAB variables. The variable **map_internal** holds its value at any given iteration into the next call. At the end of the function, the **mapOut** is updated and then displayed.
